

Welcome - CSC 301

CSC 301- Fundamentals of Programming Languages

- Instructor: Dr. Lutz Hamel
- Email: lutzhamel@uri.edu
- Book: “Modern Programming Languages”, **any edition**
- (for more details see BrightSpace)

Why Study Programming Languages?

- Amazing variety
 - ~2300 different programming languages discussed on online forums*.
- “Strange” controversies
 - Should a programming language have a ‘goto’ statement?
 - Should an OO language support inheritance?
 - Terminology: argument vs. actual parameter.
- Many connections
 - Programming languages touch upon virtually all areas of computer science: from the mathematical theory of **formal languages** and **automata** to the implementation of **operating systems**.
- Intriguing evolution
 - Programming languages change!
 - New ideas and experiences trigger new languages.
 - New languages trigger new ideas, etc.

Reading

- Chap 1 in “Modern Programming Languages” (MPL)

Programming Language Classes

There are many different programming language classes, but three classes or paradigms stand out:

- Imperative Languages
- Functional Languages
- Logic/Rule Based Languages

What Happened to OOP?

- Object-orientation is really a property of the type system of a language.
- OO features have traditionally been added to imperative languages (C++, Java, Python)
- Object-oriented features have also been added to:
 - Functional programming languages like Lisp (CLOS)
 - Logic languages like Prolog (Logtalk)
- Here we look at object-based programming within the multi-paradigm language Asteroid

Meet Our Languages

- Asteroid – An object-based, imperative, and functional programming language being developed right here at URI
 - <https://asteroid-lang.org>
- Prolog – A logic programming language, most famously used in IBM Watson
 - The IBM Watson knowledge base was filled with 200 million pages of information, including the entire Wikipedia website. To parse the questions into a form that IBM Watson could understand, the IBM team used Prolog to parse natural-language questions into new facts that could be used in the IBM Watson pipeline. In 2011, the system competed in the game *Jeopardy!* and defeated former winners of the game.

Example Computation

- Recursive definition of the factorial operator

$$x! = \begin{cases} 1 & \text{if } x = 1, \\ x(x-1)! & \text{otherwise.} \end{cases}$$

for all $x > 0$.

Imperative Languages

- Hallmarks: assignment and iteration
- Examples: C, FORTRAN, Imperative sublanguage of Asteroid
- Example Program: factorial program in (imperative) Asteroid

```
function fact with n do
  let val = 1.
  while n > 1 do
    let val = val*n.
    let n = n-1.
  end
  return val.
end
```

Imperative Languages

Observations:

- The program text determines the order of execution of the statements.
- We have the notion of a ‘*current value*’ of a variable – accessible state of variable.

This is not always true in other languages.

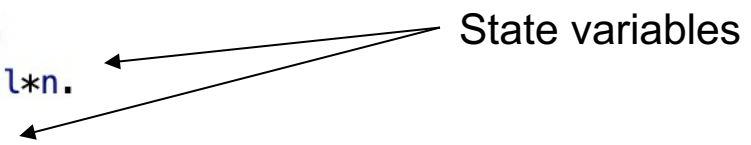

Imperative Asteroid

```
-- compute the factorial

load system io.

function fact with n do
  let val = 1.
  while n > 1 do
    let val = val*n.
    let n = n-1.
  end
  return val.
end

let x = tointeger(io @input("Enter a positive integer: ")).
io @println ("The factorial of " + tostring(x) + " is " + tostring(fact x)).
```

State variables

In001/fact-iter.ast

Functional Languages

- Hallmarks: recursion, multi-dispatch, single valued variables.
- Examples: ML, Lisp, Haskell, Functional sublanguage of Asteroid
- Example Program: factorial program in (functional) Asteroid

multi-dispatch {

```
function fact
  with 1 do
    return 1
  with n do
    return n*fact(n-1).
  end
```

} n is single valued variable.

recursion ↗

Functional Languages

Observations:

- **No** explicit assignments necessary
 - we will allow them later for convenience sake but they will introduce only single valued variables
- The name stems from the fact that programs consist of *recursive* definitions of **functions**.

Functional Asteroid

```
-- compute the factorial

load system io.

function fact
  with 1 do
    return 1
  with n do
    return n*fact(n-1).
  end

let x = tointeger(io @input("Enter a positive integer: ")).
io @println ("The factorial of " + tostring(x) + " is " + tostring(fact x)).
```

In001/fact-rec.ast

Logic Programming Languages

- Hallmarks: programs consist of **rules** that specify the problem solution.
- Examples: Prolog, Maude, Isabelle
- Example Program: factorial program written in Prolog

rules {

```
fact(1,1).                                     fact(in,out)
fact(X,F) :-
  X1 is X-1, ← 'and'
  fact(X1,F1),
  F is X*F1.
```

Logic Programming Languages

Observations:

- Rules do *not* appear in the order of execution in the program text.
- No specific order of execution is given – rules ‘fire’ when necessary.

Prolog

```
% factorial program
```

```
fact(1,1).
```

```
fact(X,F) :-
```

```
    X1 is X-1,
```

```
    fact(X1,F1),
```

```
    F is X*F1.
```

```
compute :-
```

```
    X is 3,
```

```
    fact(X,F),
```

```
    writeln(F).
```

Object-Based Languages

- Hallmarks: bundle data with the allowed operations ➔ Objects
- Asteroid takes an interesting approach here – structures with functions.

```
-- simple object-based program

load system io.

-- define our rectangular structure with member functions
structure Rect with
  data xdim.
  data ydim.

  -- return the area of the rectangle
  function area with none do
    return this @xdim * this @ydim.
  end
end

let r = Rect(4,2).
let x = tostring(r@xdim).
let y = tostring(r@ydim).
let area = tostring(r@area()).
io @println ("The area of rectangle <" + x + "," + y + "> is " + area).
```

In001/rect.ast

Programming Language Classes

General Observations:

- Programming languages guide programmers towards a particular programming style:
 - Imperative → iteration/assignment
 - Functional → mathematical functions
 - OO → objects
 - Logic → rules
- Programming itself guides the developer towards new language ideas:
 - Recursion was introduced by John McCarthy in the 1950' s with the programming language Lisp to solve problems in AI.
 - Classes and objects were developed by Nygaard and Dahl in the 1960' s and 70' s for the language Simula in order to solve problem in simulations.

Take Away

- There exist many programming languages today (> 2000)
- In order to understand the similarities and differences \Rightarrow sort into *classes*
 - Imperative
 - assignment and iteration
 - Functional
 - Recursion, single valued variables
 - Logic/rule based
 - programs consist of rules
- Object-based
 - bundle data with the allowed operations

Reading & Assignments

- Reading: Modern Programming Languages (MPL) Chap 1.
- Install Asteroid
